

For our High-Fidelity Prototype, we considered several concepts discussed in class: affordances, signifiers, and conceptual models. Regarding our site's affordances; the relation between a design's properties and the user's capabilities; we ensured that potential user actions were not simply limited to reading text and navigating the site via embedded links. Our site prototype also enables users to skim through slideshows, trigger Q&A pop-ups, conduct a word search for the entire site, fill out overlay forms, watch videos, and more.

Although not all these affordances have been made accessible due to some components still being inactive on the prototype, our group will be able to rectify this issue when we draft the final version of the site on WordPress. As for signifiers, a means of communicating what actions a user can take as well as where, we ensured that all interactable elements of the prototype had appropriate symbols to guide the user on where to toggle or accurately convey the function of each of them.

In designing our high-fidelity prototype, we were also aware of the concept of conceptual models. Conceptual models can be best defined as the visible explanation of how certain systems work. These models can embody the form of manuals or preconceived knowledge working in conjunction with mental images. Because the user won't have the luxury of a manual, we ensured that when designing the interactable components, we used designs and animations similar to pre-existing systems to account for user familiarity and implement interactivity designs that accounted for user error, enabling the Q&A buttons to be triggered not only by the arrow button but also by clicking the question itself.
